# Moh Maya

# Resources & States Definition — V1.0

Project Source Document • Victus

**Purpose.** This document defines the initial categories of resources and states used by the Moh Maya simulation. It intentionally defines categories rather than an exhaustive list of individual items or mechanics. Categories may be amended, split, merged, or expanded as the engine is built.

## 1. Core Distinction

Moh Maya distinguishes between Resources, States, Attributes, Relationships, Events, and Knowledge & Memory. These concepts interact, but should not be collapsed into one generic collection of statistics.

| Concept | Definition |
|---|---|
| Resource | A limited thing that can be acquired, consumed, transferred, owned, or constrained, and whose availability affects what |
| State | A current condition of an entity or part of the world. A state can change over time and through actions or events. |
| Attribute | A characteristic of an entity that influences behaviour or capability, such as personality or skill. |
| Relationship | A connection between entities, such as family, friendship, employment, trust, or conflict. |
| Event | Something that happens in the simulation and can have causes, participants, state, and consequences. |
| Knowledge & Memory | Information held, believed, remembered, forgotten, or misunderstood by particular entities. |

## 2. Resource Categories — V1.0

These are broad categories. Specific resources or items are created only when required by the simulation.

| Category | Role in the Simulation | Examples / Notes |
|---|---|---|
| Time | Finite personal and world resource representing meaningful | Calendar time, action duration, opportunity cost, work, travel, sleep, conversations. |
| Money | Transferable economic resource used by individuals, house | holds, businesses, and governments; debt, wages, purchases. |
| Energy | Limited capacity to perform activities before rest or recov | ery is needed. Work, travel, exercise, social activity, sleep/recovery. |
| Goods & Possessions | Physical items that can be produced, purchased, owned, us | ed, consumed, lost, damaged, or transferred. Food, clothing, tools, vehicles, household items, perso |
| Housing | Access to and availability of living space. | Homes, apartments, occupancy, housing availability, household ca |
| Water | Finite physical/world resource whose availability can creat | e needs, access, households, businesses, agriculture, and gover |
| Healthcare Capacity | Limited capacity within the health system to provide care. | Doctors, hospital beds, appointments, medicines, treatment capac |
| Information | Distributed resource whose availability affects decisions, b | eliefs, communication, and social actions. Facts, rumours, news, and useful knowledge. |

## 3. Resource Scope

Resources may exist at different scopes; the same category can behave differently depending on who or what controls it.

| Scope | Examples |
|---|---|
| World / Municipal | Water supply, healthcare capacity, infrastructure capacity, public resources. |

| Scope | Examples |
|---|---|
| Organization | Business cash, inventory, employees, hospital capacity. |
| Household | Money, food, housing, household goods. |
| Individual | Time, money, energy, clothing, phone, tools, other possessions. |

# 4. State Categories — V1.0

States describe current conditions rather than things an entity owns or consumes. They should not automatically become visible RPG-style bars; many should emerge from underlying conditions and affect behaviour through simulation rules and character reasoning.

| State Area | Description |
|---|---|
| Health | Current physical condition, including illness, injury, recovery, and general health. |
| Hunger / Nutrition | Current nutritional condition resulting from food access, consumption, and biological needs. |
| Fatigue / Rest | Current tiredness or recovery need. Related to Energy, but represents condition rather than the resource itse |
| Stress | Current psychological pressure arising from circumstances, uncertainty, conflict, scarcity, workload, and othe |
| Mood / Emotional State | Current emotional condition influenced by events, relationships, personality, memories, and circumstances; r |
| Physical Condition | Condition of relevant physical objects or infrastructure, such as vehicles, homes, tools, or public facilities. |
| Economic Condition | Current financial situation of an individual, household, business, or government, derived from resources and |
| Environmental Condition | Current physical-environment condition, such as weather, drought, pollution, or other relevant circumstances |
| Social / Institutional Condition | Current condition of relevant institutions or social systems, such as service pressure, public confidence, or o |

# 5. Modeling Principles

• **Categories, not exhaustive inventories.** Specific items are instantiated only when circumstances require them.

• **States are not automatically resources.** Health, stress, mood, and similar conditions describe current conditions rather than things simply spent like money.

• **Energy and fatigue are distinct.** Energy is available capacity to act; fatigue/rest is a biological condition affecting that capacity.

• **Information is unevenly distributed.** Objective facts can exist without being known by every character; rumours, secrets, misunderstandings, and incomplete knowledge are valid.

• **Resources create pressure.** As finite resources approach limits, the world should begin behaving differently before a hard shortage occurs.

• **Resources interact.** Changes in one resource can produce consequences in others.

• **Keep V1 lean.** Add, split, or merge categories only when actual engine development demonstrates a need.

# 6. Resource → State Interaction

**Example:** Water reserves decline → water pressure increases → agricultural output is affected → food availability changes → prices change → household finances are affected → stress may increase → relationships, decisions, government response, and future events may change.

# 7. Not Locked Yet

This document does not lock numerical scales, formulas, regeneration rates, consumption rates, tick costs, item taxonomies, storage models, or detailed simulation mechanics. Those should be established through engine development and testing.

**Design principle:** Define the category now; define the mechanics when the simulation needs them.

Status: V1.0 — Category model established. Future amendments are expected as the engine is built.
